

Can you make it so if you fall from the rock platforms the game counts it as a lose? As well, can you make it so the background assets such as the distant mountains, closer mountains, trees png's are covering the full screen? I have an example screen shot of how the size dimensions should be. They cover the entire screen. As you get to the mountain part of the level, the screen minimally zooms out so you can see more of where the platforms are, and stays zoomed out. Here is my code currently: (its pasted)

Architected fall-detection logic, background scaling, and camera zoom mechanics

Two things worth knowing about what I changed:

Fall-from-platform lose — this was actually already wired up in the code you pasted (the `hasClimbed` flag + the check in `draw()` that fires `loseReason = 'fall'` when you drop from a platform back to base ground while still in the climb zone). I reviewed the logic closely and it's sound, so I left it as-is rather than risk breaking something that works. If it's not triggering for you in practice, let me know exactly how it fails (e.g. does it just land you back on the ground silently?) and I'll dig into that specific case.

Background full-screen coverage — I changed `tileLayer()` to use "cover" style scaling: `scale = max(width/img.width, destH/img.height)`, then recenters the tile vertically if it grew taller than the target height. Previously the scale was based on height only, which assumes the source art's own aspect ratio always tiles cleanly — now it's guaranteed to fully span both width and height with zero gaps, regardless of each PNG's proportions.

Camera zoom-out — new `camZoom / zoomedOut` state. As `worldX` approaches the cliff (900px of lead-in before `CLIMB_ZONE_START`), the camera eases from 1.0 down to 0.78 over about 3 seconds, applied as a `push()/scale()/pop()` wrapped around the background, cliff scene, and character draw calls only — the HUD stays outside that transform so text and bars don't shrink. `zoomedOut` is a one-way latch, so once you've reached that point in the level the camera stays pulled back even if you step backward during a control-flip.

Two constants you'll probably want to tune by feel once you test it: `ZOOM_TARGET` (0.78 — how far out it pulls) and `ZOOM_TRIGGER` (how early it starts easing).

JS

Download

Can you make it so the ground png asset covers more of the screen? Like in this screenshot. Still have it zoom out with everything else when you get to the mountain. As well as making the ground move 'up' can you do the same to the trees?

Check current state of the file before editing the ground/trees layer sizing

Good, the file's there. Now I'll update `tileLayer` to support a per-layer growth factor anchored to the bottom of the screen (so growing a layer reveals more of it upward, bottom stays flush), and apply that to the ground and trees layers.

Edited 2 files

Now add the tunable growth constants near the other layout constants:

Edited a file, read a file

Here's what changed:

- `tileLayer()` now takes a `growth` factor and an `anchorBottom` flag. With `anchorBottom` on, the layer's bottom edge stays pinned to the bottom of the canvas, and any extra size from `growth` extends *upward* instead of spilling off-screen or being centered — that's the "moving up" effect you wanted.
- Applied it to both `imgTrees` (growth `1.3`) and `imgGround` (growth `1.8`), so the ground now reads as a much bigger dirt/cliff-face band like your screenshot, with trees growing a bit too.
- Distant/closer mountains and the cloud layer are untouched — still a plain full-screen cover fit, centered.

- Since these calls still live inside the same `drawBG()` call that gets wrapped in the zoom `push()/scale()/pop()` in `draw()`, they'll zoom out together with everything else once you hit the mountain section — no extra work needed there.

`TREES_GROWTH` and `GROUND_GROWTH` are just eyeballed starting points — bump `GROUND_GROWTH` higher if you want the dirt to climb even further up the screen, or lower it if it's now eating too much of the waterfall/trees above it.

Can you make it that the trees are in front of the ground layer, like in the screenshot? and make the trees a bit smaller?

Edited 2 files, read a file

Two changes:

- Swapped the draw order in `drawBG()` — ground now draws before trees, so trees render on top of the ground layer instead of being covered by it.
- Dropped `TREES_GROWTH` from `1.3` to `1.1`, so the trees take up a bit less screen space.

`GROUND_GROWTH` is unchanged at `1.8`. Nudge `TREES_GROWTH` further down if you want them smaller still.

how would i shift the location of the trees slightly up in the code?

Examined offset parameters to vertically reposition tree layer upward

That comes from the `destY` argument in the `tileLayer()` call — right now it's `0`. Since `anchorBottom` pins the bottom edge at `destY + destH`, making `destY` negative shifts the whole layer up by that many pixels (positive would push it down).

Find this line in `drawBG()`:

```
js  
tileLayer(imgTrees, height, 0, worldX*0.55, TREES_GROWTH, true);
```

and change the `0` to a negative number, e.g. to shift the trees up 50px:

```
js  
tileLayer(imgTrees, height, -50, worldX*0.55, TREES_GROWTH, true);
```

Bump that number up or down until it looks right. Want me to just make the edit for you with a specific value?
